Description

[0001] The present invention is in the field of conversion processes using immobilized enzymes, produced by genetic engineering.

Background of the invention

[0002] In the detergent, personal care and food products industry there is a strong trend towards natural ingredients of these products and to environmentally acceptable production processes. Enzymic conversions are very important for fulfilling these consumer demands, as these processes can be completely natural. Moreover enzymic processes are very specific and consequently will produce minimum amounts of waste products. Such processes can be carried out in water at mild temperatures and atmospheric pressure. However enzymic processes based on free enzymes are either quite expensive due to the loss of enzymes or require expensive equipment, like ultra-membrane systems to entrap the enzyme.

[0003] Alternatively enzymes can be immobilized either physically or chemically. The latter method has often the disadvantage that coupling is carried out using non-natural chemicals and in processes that are not attractive from an environmental point of view. Moreover chemical modification of enzymes is nearly always not very specific, which means that coupling can affect the activity of the enzyme negatively.

[0004] Physical immobilization can comply with consumer demands, however also physical immobilization may affect the activity of the enzyme in a negative way. Moreover, a physically immobilized enzyme is in equilibrium with free enzyme, which means that in continuous reactors, according to the laws of thermodynamics, substantial losses of enzyme are unavoidable.

[0005] There are a few publications on immobilization of enzymes to microbial cells (see reference 1). The present invention provides a method for immobilizing enzymes to cell walls of microbial cells in a very precise way. Additionally, the immobilization does not require any chemical or physical coupling step and is very efficient.

[0006] Some extracellular proteins are known to have special functions which they can perform only if they remain bound to the cell wall of the host cell. Often this type of protein has a long C-terminal part that anchors it in the cell wall. These C-terminal parts have very special amino acid sequences. A typical example is anchoring via C-terminal sequences enriched in proline (see reference 2). Another mechanism to anchor proteins in cell walls is that the protein has a glycosyl-phosphatidyl-inositol (GPI) anchor (see reference 3) and that the C-terminal part of the protein contains a substantial number of potential serine and threonine glycosylation sites.

[0007] O-Glycosylation of these sites gives a rod-like conformation to the C-terminal part of these proteins. Another feature of these manno-proteins is that they seem to be linked to the glucan in the cell wall of lower eukaryotes, as they cannot be extracted from the cell wall with SDS, but can be liberated by glucanase treatment.

Summary of the invention

[0008] The invention relates to use of a lower eukaryote selected from the group consisting of yeasts and fungi containing an expressible first polynucleotide comprising a structural gene encoding a protein providing catalytic activity, said protein being immobilised at the exterior of the cell wall of said lower eukaryote, and at least part of a gene encoding an anchoring protein capable of anchoring in the cell wall of said lower eukaryote, said part encoding at least the anchoring part of said anchoring protein, which anchoring part is derivable from the C-terminal half of said anchoring protein, said first polynucleotide being present in either a vector or in a chromosome of said lower eukaryote, for carrying out an enzymatic process, by contacting a substrate for the protein providing catalytic activity, with the lower eukaryote.

[0009] The invention relates to the use of a recombinant polynucleotide comprising a structural gene encoding a protein providing catalytic activity and at least a part of a gene encoding a protein capable of anchoring in a eukaryotic or prokaryotic cell wall, said part encoding at least the C-terminal part of said anchoring protein for carrying out an enzymatic process. Preferably the polynucleotide further comprises a sequence encoding a signal peptide ensuring secretion of the expression product of the polynucleotide. Such signal peptide can be derived from a glycosyl-phosphatidyl-inositol (GPI) anchoring protein, α -factor, α -agglutinin, invertase or inulinase, α -amylase of *Bacillus*, or a proteinase of lactic acid bacteria. The DNA sequence encoding a protein capable of anchoring in the cell wall can encode α -agglutinin, AGA1, FLO1 or the Major Cell Wall Protein of lower eukaryotes, or a proteinase of lactic acid bacteria. The recombinant polynucleotide is operably linked to a promoter, preferably an inducible promoter. The DNA sequence encoding a protein providing catalytic activity can encode a hydrolytic enzyme, e.g. a lipase, or an oxidoreductase, e.g. an oxidase. Another embodiment of the invention relates to a recombinant vector comprising a polynucleotide as described above. If such vector contains a DNA sequence encoding a protein providing catalytic activity, which protein exhibits said catalytic activity when present in a multimeric form, said vector can further comprise a second polynucleotide comprising a structural gene encoding the same protein providing catalytic activity combined with a sequence

encoding a signal peptide ensuring secretion of the expression product of said second polynucleotide, said second polynucleotide being operably linked to a regulatable promoter, preferably an inducible or repressible promoter.

[0010] If the protein providing catalytic activity exhibits said catalytic activity when present in a multimeric form, said host cell or microorganism can further comprise a second polynucleotide comprising a structural gene encoding the same protein providing catalytic activity combined with a sequence encoding a signal peptide ensuring secretion of the expression product of said second polynucleotide, said second polynucleotide being operably linked to a regulatable promoter, preferably an inducible or repressible promoter, and said second polynucleotide being present either in another vector or in the chromosome of said microorganism. Preferably the host cell or microorganism has at least one of said polynucleotides integrated in its chromosome. As a result of culturing such host cell or microorganism the invention provides a host cell, preferably a microorganism, having a protein as described above immobilized on its cell wall. The host cell or microorganism can be a lower eukaryote, in particular a yeast.

[0011] The invention provides a process for carrying out an enzymatic process by using an immobilized catalytically active protein, wherein a substrate for said catalytically active protein is contacted with a host cell or microorganism according to the invention.

Detailed description of the invention

[0013] The present invention provides a method for immobilizing an enzyme, comprising immobilizing the enzyme or a functional part thereof to the cell wall of a host cell, preferably a microbial cell, using recombinant DNA techniques. In particular, the C-terminal part of a protein that ensures anchoring in the cell wall is linked to an enzyme or the functional part of an enzyme, in such a way that the enzyme is localized on or just above the cell surface. In this way immobilized enzymes are obtained on the surface of cells. The linkage is performed at gene level and is characterized in that the structural gene coding for the enzyme is coupled to at least part of a gene encoding an anchor-protein in such a way that in the expression product the enzyme is coupled at its C-terminal end to the C-terminal part of an anchor-protein. The chimeric enzyme is preferably preceded by a signal sequence that ensures efficient secretion of the chimeric protein.

[0014] Thus the invention relates to a recombinant polynucleotide comprising a structural gene encoding a protein providing catalytic activity and at least a part of a gene encoding a protein capable of anchoring in a eukaryotic or prokaryotic cell wall, said part encoding at least the C-terminal part of said anchoring protein. The length of the C-terminal part of the anchoring protein may vary. Although the entire structural protein could be used, it is preferred that only a part is used, leading to a more efficient exposure of the enzyme protein in the medium surrounding the cell. The anchoring part of the anchoring protein should preferably be entirely present. As an example, about the C-terminal half of the anchoring protein could be used.

[0015] Preferably, the polynucleotide further comprises a sequence encoding a signal peptide ensuring secretion of

the expression product of the polynucleotide. The signal peptide can be derived from a GPI anchoring protein, α -factor, α -agglutinin, invertase or inulinase, α -amylase of *Bacillus*, or a proteinase of lactic acid bacteria.

[0016] The protein capable of anchoring in the cell wall is preferably selected from the group of α -agglutinin, AGA1, FLO1 (flocculation protein) or the Major Cell Wall Protein of lower eukaryotes, or a proteinase of lactic acid bacteria.

The polynucleotide of the invention is preferably operably linked to a promoter, preferably a regulatable promoter, especially an inducible promoter.

[0017] The invention also relates to a recombinant vector containing the polynucleotide as described above, and to a host cell containing this polynucleotide, or this vector.

[0018] In a particular case, wherein the protein providing catalytic activity exhibits said catalytic activity when present in a multimeric form, such as may be the case with oxidoreductases, dimerisation or multimerisation of the monomers might be a prerequisite for activity. The vector and/or the host cell can then further comprise a second polynucleotide comprising a structural gene encoding the same protein providing catalytic activity combined with a sequence encoding a signal peptide ensuring secretion of the expression product of said second polynucleotide, said second polynucleotide being operably linked to a regulatable promoter, preferably an inducible or repressible promoter. Expression and secretion of the second polynucleotide after expression and secretion of the first polynucleotide will then result in the formation of an active multimer on the exterior of the cell wall.

[0019] The host cell or microorganism preferably contains the polynucleotide described above, or at least one of said polynucleotides in the case of a combination, integrated in its chromosome.

[0020] The present invention relates to lower eukaryotes like yeasts that have very stable cell walls and have proteins that are known to be anchored in the cell wall, e.g. α -agglutinin or the product of gene *FLO1*. Suitable yeasts belong to the genera *Candida*, *Debaryomyces*, *Hansenula*, *Kluyveromyces*, *Pichia* and *Saccharomyces*.

[0021] Also fungi, especially *Aspergillus*, *Penicillium* and *Rhizopus* can be used. For certain applications also prokaryotes are applicable.

[0022] For yeasts the present invention deals in particular with genes encoding chimeric enzymes consisting of:

- a. the signal sequence e.g. derived from the α -factor-, the invertase-, the α -agglutinin- or the inulinase genes;
- b. structural genes encoding hydrolytic enzymes such as α -galactosidase, proteases, peptidases, pectinases, pectylesterase, rhamnogalacturonase, esterases and lipases, or non-hydrolytic enzymes such as oxidases; and
- c. the C-terminus of typically cell wall bound proteins such as α -agglutinin (see reference 4), AGA1 (see reference 5) and FLO1 (see the non-prior published reference 6).

[0023] The expression of these genes can be under the control of a constitutive promoter, but more preferred are regulatable, i.e. repressible or inducible promoters such as the *GAL7* promoter for *Saccharomyces*, or the inulinase promoter for *Kluyveromyces* or the methanol-oxidase promoter for *Hansenula*.

[0024] Preferably the constructs are made in such a way that the new genetic information is integrated in a stable way in the chromosome of the host cell.

[0025] The invention further relates to a host cell, in particular a microorganism, having the chimeric protein described above immobilized on its cell wall. It concerns the use of such microorganisms for carrying out an enzymatic process by contacting a substrate for the enzyme with the microorganism. Such a process may be carried out e.g. in a packed column, wherein the microorganisms may be supported on solid particles, or in a stirred reactor. The reaction may be aqueous or non-aqueous. Where necessary, additives necessary for the performance of the enzyme, e.g. a co-factor, may be introduced in the reaction medium.

[0026] After repeated usage of the naturally immobilized enzyme system in processes, the performance of the system may decrease. This is caused either by physical denaturation or by chemical poisoning or detachment of the enzyme. A particular feature of the present invention is that after usage the system can be recovered from the reaction medium by simple centrifugation or membrane filtration techniques and that the thus collected cells can be transferred to a recovery medium in which the cells revive quickly and concomitantly produce the chimeric protein, thus ensuring that the surface of the cells will be covered by fully active immobilized enzyme. This regeneration process is simple and cheap and therefore will improve the economics of enzymic processes and may result in a much wider application of processes based on immobilized enzyme systems.

[0027] However, by no means the present invention is restricted to the reusability of the immobilized enzymes.

[0028] The invention will be illustrated by the following examples without the scope of the invention being limited thereto.

EXAMPLE 1 Immobilized α -galactosidase/ α -agglutinin on the surface of *S. cerevisiae*.

[0029] The gene encoding α -agglutinin has been described by Lipke *et al.* (see reference 4). The sequence of a 6057 bp *HindIII* insert in pTZ18R, containing the whole AGA1 gene is given in Figure 1. The coding sequence expands

over 650 amino acids, including a putative signal sequence starting at nucleotide 3653 with ATG. The unique *NheI* site cuts the DNA at position 988 of the given coding sequence within the coding part of amino acid 330, thereby separating the α -agglutinin into an N-terminal and a C-terminal part of about same size.

[0030] Through digestion of pUR2968 (see Figure 2) with *NheI/HindIII* a 1.4 kb fragment was released, containing the sequence information of the putative cell wall anchor. For the fusion to α -galactosidase the plasmid pSY16 was used, an episomal vector based on YEplac 181, harbouring the α -galactosidase sequence preceded by the *SUC2* invertase signal sequence and placed between the constitutive *PGK* promoter and *PGK* terminator. The *StyI* site, present in the last nine base-pairs of the open reading frame of the α -galactosidase gene, was ligated to the *NheI* site of the *AG α 1* gene fragment. To ensure the in frame fusion, the *StyI* site was filled in and the 5' overhang of the *NheI* site was removed, prior to ligation into the *StyI/HindIII* digested pSY13 (see Figure 2).

[0031] To verify the correct assembly of the new plasmid, the shuttle vector was transformed into *E. coli* JM109 (*recA1 supE44 endA1 hsdR17 gyrA96 relA1 thi Δ (lac-proAB) F' [traD36 proAB⁺ lac^P lacZ Δ M15]*) (see reference 7) by the transformation protocol described by Chung *et al.* (see reference 8). One of the positive clones, designated pUR2969, was further characterized, the DNA isolated and purified according to the Quiagen protocol and subsequently characterized by DNA sequencing. DNA sequencing was mainly performed as described by Sanger *et al.* (see reference 9), and Hsiao (see reference 10), here with the Sequenase version 2.0 kit from United States Biochemical Company, according to the protocol with T7 DNA polymerase (Amersham International plc) and [³⁵S]dATP α S (Amersham International plc: 370 MBq/ml; 22 TBq/mmol).

[0032] This plasmid was then transformed into *S. cerevisiae* strain MT302/1C according to the protocol from Klebe *et al.* (see reference 11).

[0033] Yeast transformants were selected on selective plates, lacking leucine, on with 40 μ l (20mg/ml DMF). X- α -Gal (5-bromo-4-chloro-3-indolyl- α -D-glucose, Boehringer Mannheim) was spread, to directly test for α -galactosidase activity (see reference 12). To demonstrate the expression, secretion, localization and activity of the chimeric protein the following analyses were performed:

1. Expression and secretion

[0034] *S. cerevisiae* strain MT302/1C was transformed with either plasmid pSY13 containing the α -galactosidase gene of *Cyamopsis tetragonoloba* or plasmid pUR2969 containing the α -galactosidase/ α -agglutinin fusion construct. During batch culture α -galactosidase activities were determined for washed cells and growth medium. The results are given in Figure 3 and Figure 4. The α -galactosidase expressed from yeast cells containing plasmid pSY13 was almost exclusively present in the growth medium (Figure 3A), whereas the α -galactosidase- α -agglutinin fusion protein was almost exclusively cell associated (Figure 4A). Moreover, the immobilized, cell wall-associated, α -galactosidase- α -agglutinin fusion enzyme had retained the complete activity over the whole incubation time, while the secreted and released enzyme lost about 90% of the activity after an incubation of 65 hours. This indicates, that the immobilization of the described enzyme into the cell wall of yeast protects the enzyme against inactivation, presumably through proteinases, and thereby increases the stability significantly. Further insight into the localization of the different gene products was obtained by Western analysis. Therefore, cells were harvested by centrifugation and washed in 10 mM Tris, HCl, pH 7.8; 1 mM PMSF at 0°C and all subsequent steps were performed at the same temperature. Three ml isolation buffer and 10 g of glass beads were added per gram of cells (wet weight). The mixture was shaken in a Griffin shaker at 50% of its maximum speed for 30 minutes. The supernatant was isolated and the glass beads were washed with 1 M NaCl and 1 mM PMSF until the washes were clear. The supernatant and the washes were pooled. The cell walls were recovered by centrifugation and were subsequently washed in 1 mM PMSF.

[0035] Non-covalently bound proteins or proteins bound through disulphide bridges were released from cell walls by boiling for 5 minutes in 50 mM Tris.HCl, pH 7.8; containing 2 % SDS, 100 mM EDTA and 40 mM β -mercaptoethanol. The SDS-extracted cell walls were washed several times in 1 mM PMSF to remove SDS. Ten mg of cell walls (wet weight) were taken up in 20 1 100 mM sodium acetate, pH 5.0, containing 1 mM PMSF. To this, 0.5 mU of the β -1,3-glucanase (Laminarase; Sigma L5144) was used as a source of β -1,3-glucanase) was added followed by incubation for 2 hours at 37 °C. Subsequently another 0.5 mU of β -1,3-glucanase was added, followed by incubation for another 2 hours at 37 °C.

[0036] Proteins were denatured by boiling for 5 minutes preceding Endo-H treatment. Two mg of protein were incubated in 1 ml 50 mM potassium phosphate, pH 5.5, containing 100 mM β -mercaptoethanol and 0.5 mM PMSF with 40 mU Endo-H (Boehringer) for 48 hours at 37 °C. Subsequently 20 mU Endo-H were added followed by 24 hours of incubation at 37 °C.

[0037] Proteins were separated by SDS-PAGE according to Laemmli (see reference 13) in 2.2.-20% gradient gels. The gels were blotted by electrophoretic transfer onto Immobilon polyvinylidene-difluoride membrane (Millipore) as described by Towbin *et al.* (see reference 14). In case of highly glycosylated proteins a subsequently mild periodate treatment was performed in 50 mM periodic acid, 100 mM sodium acetate, pH 4.5, for several hours at 4 °C. All

subsequent incubations were carried out at room temperature. The blot was blocked in PBS, containing 0.5% gelatine and 0.5% Tween-20, for one hour followed by incubation for 1 hour in probe buffer (PBS, 0.2% gelatine, 0.1% Tween-20) containing 1:200 diluted serum. The blot was subsequently washed several times in washing buffer (PBS; 0.2% gelatine; 0.5% Tween-20) followed by incubation for 1 hour in probe-buffer containing 125 I-labelled protein A (Amersham). After several washes in washing buffer, the blot was air-dried, wrapped in Saran (Dow) and exposed to X-omat S film (Kodak) with intensifying screen at -70°C . An Omnimedia 6cx scanner and the Adobe Photoshop programme were used to quantify the amount of labelled protein. The results of the various protein isolation procedures from both transformants are given in Figure 5. While for the transformants comprising the pSY13 plasmid the overall mass of the enzyme was localized in the medium, with only minor amounts of enzyme more entrapped than bond in the cell wall (Figure 5A) -which could completely be removed by SDS extraction- the fusion protein was tightly bound to the cell wall; with only small amounts of α -galactosidase/ α -agglutinin delivered into the surrounding culture fluid or being SDS extractable. In contrast to the laminarinase extraction of cell walls from cells expressing the free α -galactosidase, where no further liberation of any more enzyme was observed, identical treatment of fusion enzyme expressing cells released the overall bulk of the enzyme. This indicates that the fusion protein is intimately associated with the cell wall glucan in *S. cerevisiae*, like α -agglutinin, while α -galactosidase alone is not. The subsequently performed EndoH treatment showed a heavy glycosylation of the fusion protein, a result, entirely in agreement with the described extended glycosylation of the C-terminal part of α -agglutinin.

2. Localization

[0038] Immunofluorescent labelling with anti- α -galactosidase serum was performed on intact cells to determine the presence and distribution of α -galactosidase/ α -agglutinin fusion protein in the cell wall. Immunofluorescent labelling was carried out without fixing according to Watzele *et al.* (see reference 15). Cells of $\text{OD}_{530}=2$ were isolated and washed in TBS (10 mM Tris.HCl, pH 7.8, containing 140 mM NaCl, 5 mM EDTA and 20 $\mu\text{g}/\text{ml}$ cycloheximide). The cells were incubated in TBS + anti- α -galactosidase serum for 1 hour, followed by several washings in TBS. A subsequent incubation was carried out with FITC-conjugated anti-rabbit IgG (Sigma) for 30 minutes. After washing in TBS, cells were taken up in 10 mM Tris.HCl, pH 9.0, containing 1 mg/ml p-phenylenediamine and 0.1 % azide and were photographed on a Zeiss 68000 microscope. The results of these analysis are given in Figure 6, showing clearly that the chimeric α -galactosidase/ α -agglutinin is localized at the surface of the yeast cell. Buds of various sizes, even very small ones very uniformly labelled, demonstrates that the fusion enzyme is continuously incorporated into the cell wall throughout the cell cycle and that it instantly becomes tightly linked.

3. Activity

[0039] To quantitatively assay α -galactosidase activity, 200 μl samples containing 0.1 M sodium-acetate, pH 4.5 and 10 mM p-nitrophenyl- α -D-galactopyranoside (Sigma) were incubated at 37°C for exactly 5 minutes. The reaction was stopped by addition of 1 ml 2% sodium carbonate. From intact cells and cell walls, removed by centrifugation and isolated and washed as described, the α -galactosidase activity was calculated using the extinction coefficient of p-nitrophenol of $18.4 \text{ cm}^2/\text{mole}$ at 410 nm. One unit was defined as the hydrolysis of 1 μmole substrate per minute at 37°C .

Table 1.

Distribution of free and immobilized α -galactosidase activity in yeast cells			
	α -Galactosidase activity (U/g F.W. cells)		
Expressed protein	Growth medium	Intact cells	Isolated cell walls
α -galactosidase	14.7	0.37	0.01
$\alpha\text{Gal}/\alpha\text{AGG}$ fusion protein	0.54	13.3	10.9

Transformed MT302/1C cells were in exponential phase ($\text{OD}_{530}=2$). One unit is defined as the hydrolysis of 1 μmole of p-nitrophenyl- α -D-galactopyranoside per minute at 37°C .

[0040] The results are summarized in Table 1. While the overall majority of α -galactosidase was distributed in the culture fluid, most of the fusion product was associated with the cells, primarily with the cell wall. Taking together the results shown in Figures 3 to 6 and in Table 1, it could be calculated that the enzymatic α -galactosidase activity of the chimeric enzyme is as good as that of the free enzyme. Moreover, during stationary phase, the activity of the α -galactosidase in the growth medium decreased, whereas the activity of the cell wall associated α -galactosidase α -agglutinin fusion remained constant, indicating that the cell associated fusion protein is protected from inactivation or proteolytic

degradation.

[0041] N.B. The essence of this EXAMPLE was published during the priority year by M.P. Schreuder *et al.* (see reference 25).

5 **EXAMPLE 2A Immobilized *Humicola* lipase/ α -agglutinin on the surface of *S. cerevisiae*. (inducible expression of immobilized enzyme system)**

[0042] The construction and isolation of the 1.4 kb *NheI*/*HindIII* fragment containing the C-terminal part of α -agglutinin has been described in EXAMPLE 1. Plasmid pUR7021 contains an 894 bp long synthetically produced DNA fragment encoding the lipase of *Humicola* (see reference 16 and SEQ ID NO: 7 and 8), cloned into the *EcoRI*/*HindIII* restriction sites of the commercially available vector pTZ18R (see Figure 7). For the proper one-step modification of both the 5' end and the 3' end of the DNA part coding for the mature lipase, the PCR technique can be applied. Therefore the DNA oligonucleotides lipo1 (see SEQ ID NO: 3) and lipo2 (see SEQ ID NO: 6) can be used as primers in a standard PCR protocol, generating an 826 bp long DNA fragment with an *EagI* and a *HindIII* restriction site at the ends, which can be combined with the larger part of the *EagI*/*HindIII* digested pUR2650, a plasmid containing the α -galactosidase gene preceded by the invertase signal sequence as described earlier in this specification, thereby generating plasmid pUR2970A (see Figure 7).

[0043] PCR oligonucleotides for the in-frame linkage of *Humicola* lipase and the C-terminus of α agglutinin.

20 a: PCR oligonucleotides for the transition between *SUC2* signal sequence and the N-terminus of lipase.

25 **primer lipo1:** 5'-GGG GCG GCC GAG GTC TCG CAA GAT CTG GA-3' **>mature lipase**
 lipase: 3'-TAA GCA GCT CTC CAG AGC GTT CTG GAC CTG TTT-5'
 (non-coding strand, see SEQ ID NO: 4)

30 b: PCR oligonucleotides for the in frame transition between C-terminus of lipase and C-terminal part of α -agglutinin.

35 **lipase:** 5'-TTC GCG TTA ATT GGG ACA TGT CTT TAG TGC GA-3'

primer 3'-CCC AAT TAA CCC TGT ACA GAA CGA TCG GAA TTC GAACCCC-5'
lipo2: *NheI* *HindIII*
 (for the part of the lipase coding strand see SEQ ID NO: 5)

40 [0044] Through the PCR method a *NheI* site will be created at the end of the coding sequence of the lipase, allowing the in-frame linkage between the DNA coding for lipase and the DNA coding for the C-terminal part of α -agglutinin. Plasmid pUR2970A can then be digested with *NheI* and *HindIII* and the 1.4 kb *NheI*/*HindIII* fragment containing the C-terminal part of α -agglutinin from plasmid pUR2968 can be combined with the larger part of *NheI* and *HindIII* treated plasmid pUR2970A, resulting in plasmid pUR2971A. From this plasmid the 2.2 kb *EagI*/*HindIII* fragment can be isolated and ligated into the *EagI*- and *HindIII*-treated pUR2741, whereby plasmid pUR2741 is a derivative of pUR2740 (see reference 17), where the second *EagI* restriction site in the already inactive *Tet* resistance gene was deleted through *NruI*/*SaI* digestion. The *SaI* site was filled in prior to religation. The ligation then results in pUR2972A containing the *GAL7* promoter, the invertase signal sequence, the chimeric lipase/ α -agglutinin gene, the 2 μ m sequence, the defective *Leu2* promoter and the *Leu2* gene. This plasmid can be used for transforming *S. cerevisiae* and the transformed cells can be cultivated in YP medium containing galactose as an inducer without repressing amounts of glucose being present, which causes the expression of the chimeric lipase/ α -agglutinin gene.

[0045] The expression, secretion, localization and activity of the chimeric lipase/ α -agglutinin can be analyzed using similar procedures as given in EXAMPLE 1.

55 [0046] In a similar way variants of *Humicola* lipase, obtained via rDNA techniques, can be linked to the C-terminal part of α -agglutinin, which variants can have a higher stability during (inter)esterification processes.

EXAMPLE 2B Immobilized *Humicola* lipase/ α -agglutinin on the surface of *S. cerevisiae* (inducible expression of immobilized enzyme system)

[0047] EXAMPLE 2A describes a protocol for preparing a particular construct. Before carrying out the work it was considered more convenient to use the expression vector described in EXAMPLE 1, so that the construction route given in this EXAMPLE 2B differs on minor points from the construction route given in EXAMPLE 2A and the resulting plasmids are not identical to those described in EXAMPLE 2A. However, the essential gene construct comprising the promoter, signal sequence, and the structural gene encoding the fusion protein are the same in EXAMPLES 2A and 2B.

1. Construction

[0048] The construction and isolation of the 1.4 kb *NheI/HindIII* fragment encoding the C-terminal part of α -agglutinin cell wall protein has been described in EXAMPLE 1. The plasmid pUR7033 (resembling pUR7021 of EXAMPLE 2A) was made by treating the commercially available vector pTZ18R with *EcoRI* and *HindIII* and ligating the resulting vector fragment with an 894 bp long synthetically produced

[0049] DNA *EcoRI/HindIII* fragment encoding the lipase of *Humicola* (see SEQ ID NO: 7 and 8, and reference 16).

[0050] For the fusion of the lipase to the C-terminal, cell wall anchor-comprising domain of α -agglutinin, plasmid pUR7033 was digested with *EagI* and *HindIII*, and the lipase coding sequence was isolated and ligated into the *EagI*- and *HindIII*-digested yeast expression vector pSY1 (see reference 27), thereby generating pUR7034 (see Figure 13). This is a 2 μ m episomal expression vector, containing the α -galactosidase gene described in EXAMPLE 1, preceded by the invertase (*SUC2*) signal sequence under the control of the inducible *GAL7* promoter.

[0051] Parallel to this digestion, pUR7033 was also digested with *EcoRV* and *HindIII*, thereby releasing a 57 bp long DNA fragment, possessing codons for the last 15 carboxyterminal amino acids. This fragment was exchanged against a small DNA fragment, generated through the hybridisation of the two chemically synthesized deoxyoligonucleotides SEQ ID NO: 9 and SEQ ID NO: 10. After annealing of both DNA strands, these two oligonucleotides essentially reconstruct the rest of the 3' coding sequence of the initial lipase gene, but additionally introduce downstream of the lipase gene a new *NheI* restriction site, followed by a *HindIII* site in close vicinity, whereby the first three nucleotides of the *NheI* site form the codon for the last amino acid of the lipase. The resulting plasmid was designated pUR2970B. Subsequently, this construction intermediate was digested with *EagI* and *NheI*, the lipase encoding fragment was isolated, and, together with the 1.4 kb *NheI/HindIII* fragment of pUR2968 ligated into the *EagI*- and *HindIII*-cut pSY1 vector. The outcome of this 3-point-ligation was called pUR2972B (see Figure 14), the final lipolase- α -agglutinin yeast expression vector.

[0052] This plasmid was used for transforming *S. cerevisiae* strain SU10 as described in reference 17 and the transformed cells were cultivated in YP medium containing galactose as the inducer without repressing amounts of glucose being present, which causes the expression of the chimeric lipase/ α -agglutinin gene.

2. Activity

[0053] To quantify the lipase activity, two activity measurements with two separate substrates were performed. In both cases, SU10 yeast cells transformed with either plasmid pUR7034 or pSY1 served as control. Therefore, yeast cell transformants containing either plasmid pSY1 or plasmid pUR7034 or plasmid pUR2972B were grown up for 24h in YNB-glucose medium supplied with histidine and uracil, then diluted 1:10 in YP-medium supplied with 5% galactose, and again cultured. After 24h incubation at 30°C, a first measurement for both assays was performed.

[0054] The first assay applied was the pH stat method. Within this assay, one unit of lipase activity is defined as the amount of enzyme capable of liberating one micromole of fatty acid per minute from a triglyceride substrate under standard assay conditions (30 ml assay solution containing 38 mM olive oil, considered as pure trioleate, emulsified with 1:1 w/w gum arabic, 20 mM calcium chloride, 40 mM sodium chloride, 5 mM Tris, pH 9.0, 30°C) in a radiometer pH stat apparatus (pHM 84 pH meter, ABU 80 autoburette, TTA 60 titration assembly). The fatty acids formed were titrated with 0.05 N NaOH and the activity measured was based on alkali consumption in the interval between 1 and 2 minutes after addition of putative enzyme batch. To test for immobilized lipase activity, 1 ml of each culture was centrifuged, the supernatant was saved, the pellet was resuspended and washed in 1 ml 1 M sorbitol, subsequently again centrifuged and resuspended in 200 μ l 1 M sorbitol. From each type of yeast cell the first supernatant and the washed cells were tested for lipase activity.

A: Lipase activity after 24h (LU/ml)		
	cell bound	culture fluid
pSY1	5.9	8.8
pUR7034	24.1	632.0
pUR2972B-(1)	18.7	59.6
pUR2972B-(2)	24.6	40.5

B: Lipase activity after 48h (LU/ml)			
	cell bound	culture fluid	OD660
pSY1	6.4	4.3	~40
pUR7034	215.0	2750.0	~40
pUR2972B-(1)	37.0	87.0	~40
pUR2972B-(2)	34.0	82.0	~40

[0055] The rest of the yeast cultures was further incubated, and essentially the same separation procedure was done after 48 hours. Dependent on the initial activity measured, the actual volume of the sample measured deviated between 25µl and 150µl.

[0056] This series of measurements indicates, that yeast cells comprising the plasmid coding for the lipase-α-agglutinin fusion protein in fact express some lipase activity which is associated with the yeast cell.

[0057] An additional second assay was performed to further confirm the immobilization of activity of lipase on the yeast cell surface. Briefly, within this assay, the kinetics of the PNP (=paranitrophenyl) release from PNP-butyrate is determined by measurement of the OD at 400 nm. Therefore, 10 ml cultures containing yeast cells with either pSY1, pUR7034 or pUR2972B were centrifuged, the pellet was resuspended in 4 ml of buffer A (0.1 M NaOAc, pH 5.0 and 1 mM PMSF), from this 4 ml 500µl was centrifuged again and resuspended in 500 µl PNB-buffer (20 mM Tris-HCl, pH 9.0, 20 mM CaCl₂, 25 mM NaCl), centrifuged once again, and finally resuspended in 400µl PNB buffer. This fraction was used to determine the cell bound fraction of lipase.

[0058] The remaining 3500µl were spun down, the pellet was resuspended in 4 ml A, to each of this, 40µl laminarinase (ex mollusc, 1.25 mU/µl) was added and first incubated for 3 hours at 37°C, followed by an overnight incubation at 20°C. Then the reaction mixture, still containing intact cells, were centrifuged again and the supernatant was used to determine the amount of originally cell wall bound material released through laminarinase incubation. The final pellet was resuspended in 400µl PNP buffer, to calculate the still cell associated part. The blank reaction of a defined volume of specific culture fraction in 4 ml assay buffer was determined, and then the reaction was started through addition of 80µl of substrate solution (100 mM PNP-butyrate in methanol), and the reaction was observed at 25°C at 400 nm in a spectrophotometer.

	cell bound activity*	activity in the medium	laminarinase extract	laminarinase extracted cells	OD660
pSY1	0.001 (116µl)	0.001	0.028	0.000	2.6
pUR7034	0.293 (220µl)	0.446	0.076	0.985	2.36
pUR2972B-(1)	0.494 (143µl)	0.021	0.170	0.208	2.10

* unless otherwise mentioned, the volume of enzyme solution added was 20µl

[0059] This result positively demonstrates that a significant amount of lipase activity is immobilized on the surface yeast cell, containing plasmid pUR2972B. Here again, incorporation took place in such a way, that the reaction was catalyzed by cell wall inserted lipase of intact cells, indicated into the exterior orientated immobilization. Furthermore, the release of a significant amount of lipase activity after incubation with laminarinase again demonstrates the presumably covalent incorporation of a heterologous enzyme through gene fusion with the C-terminal part of α-agglutinin.

3. Localization

[0060] The expression, secretion, and subsequent incorporation of the lipase-α-agglutinin fusion protein into the

yeast cell wall was also confirmed through immunofluorescent labelling with anti-lipolase serum essentially as described in EXAMPLE 1, item 2. Localization.

[0061] As can be seen in Figure 15, the immunofluorescent stain shows essentially an analogous picture as the α -galactosidase immuno stain, with clearly detectable reactivity on the outside of the cell surface (see Figure 15 A showing a clear halo around the cells and Figure B showing a lighter circle at the surface of the cells), but neither in the medium nor in the interior of the cells. Yeast cells expressing pUR2972B, the *Humicola* lipase- α -agglutinin fusion protein, become homogeneously stained on the surface, indicating the virtually entire immobilization of a chimeric enzyme with an α -agglutinin C-terminus on the exterior of a yeast cell. In the performed control experiment SU10 yeast cells containing plasmid pUR7034 served as a control and here, no cell surface bound reactivity against the applied anti-lipase serum could be detected.

[0062] In a similar way variants of *Humicola* lipase, obtained via rDNA techniques, can be linked to the C-terminal part of α -agglutinin, which variants can have a higher stability during (inter)esterification processes.

EXAMPLE 3 Immobilized *Humicola* lipase/ α -agglutinin on the surface of *S. cerevisiae* (constitutive expression of immobilized enzyme system)

[0063] Plasmid pUR2972 as described in EXAMPLE 2 can be treated with *EagI* and *HindIII* and the about 2.2 kb fragment containing the lipase/ α -agglutinin gene can be isolated. Plasmid pSY16 can be restricted with *EagI* and *HindIII* and between these sites the 2.2 kb fragment containing the lipase/ α -agglutinin fragment can be ligated resulting in pUR2973. The part of this plasmid that is involved in the production of the chimeric enzyme is similar to pUR2972 with the exception of the signal sequence. Whereas pUR2972 contains the SUC2-invertase-signal sequence, pUR2973 contains the α -mating factor signal sequence (see reference 18). Moreover the plasmid pUR2973 contains the *Leu2* marker gene with the complete promoter sequence, instead of the truncated promoter version of pUR2972.

EXAMPLE 4 Immobilized *Geotrichum* lipase/ α -agglutinin on the surface of *S. cerevisiae*

[0064] The construction and isolation of the 1.4 kb *NheI/HindIII* fragment comprising the C-terminal part of AG α -1 (α -agglutinin) gene has been described in EXAMPLE 1. For the in-frame gene fusion of the DNA coding for the C-terminal membrane anchor of α -agglutinin to the complete coding sequence of *Geotrichum candidum* lipase B from strain CMICC 335426 (see Figure 8 and SEQ ID NO: 11 and 12), the plasmid pUR2974 can be used. This plasmid, derived from the commercially available pBluescript II SK plasmid, contains the cDNA coding for the complete *G. candidum* lipase II on an 1850 bp long *EcoRI/XhoI* insert (see Figure 9).

[0065] To develop an expression vector for *S. cerevisiae* with homologous signal sequences, the N-terminus of the mature lipase B was determined experimentally by standard techniques. The obtained amino acid sequence of "Gln-Ala-Pro-Thr-Ala-Val..." is in complete agreement with the cleavage site of the signal peptidase on the *G. candidum* lipase II (see reference 19).

[0066] For the fusion of the mature lipase B to the *S. cerevisiae* signal sequences of SUC2 (invertase) or α -mating factor (prepro- α MF) on one hand and the in-frame fusion to the 3' part of the AG α 1 gene PCR technique can be used. The PCR primer lipo3 (see SEQ ID NO: 13) can be constructed in such a way, that the originally present *EagI* site in the 5'-part of the coding sequence (spanning codons 5-7 of the mature protein) will become inactivated without any alteration in the amino acid sequence.

[0067] To facilitate the subsequent cloning procedures, the PCR primer can further contain a new *EagI* site at the 5' end, for the in-frame ligation to SUC2 signal sequence or prepro- α MF sequence, respectively. The corresponding PCR primer lipo4 (see SEQ ID NO: 16) contains an extra *NheI* site behind the nucleotides coding for the C-terminus of lipase B, to ensure the proper fusion to the C-terminal part of α -agglutinin.

PCR oligonucleotides for the in frame linkage of *G. candidum* lipase II to the SUC2 signal sequence and the C-terminal part of α -agglutinin.

[0068] The PCR product with the modified ends can be generated by standard PCR protocols, using instead of the normal *Ampli-Taq* polymerase the new thermostable VENT polymerase, which also exhibits proofreading activity, to ensure an error-free DNA template. Through digestion of the formerly described plasmid pUR2972 with *EagI* (complete) and *NheI* (partial), the *Humicola* lipase fragment can be exchanged against the DNA fragment coding for lipase B, thereby generating the final *S. cerevisiae* expression vector pUR2975 (see Figure 9).

[0069] The *Humicola* lipase- α -agglutinin fusion protein coding sequence can be exchanged against the lipase B/ α -agglutinin fusion construct described above by digestion of the described vector pUR2973 with *EagI*/*HindIII*, resulting in pUR2976 (see Figure 9).

EXAMPLE 5 Immobilized *Rhizomucor miehei* lipase/ α -agglutinin on the surface of *S. cerevisiae*

[0070] The construction and isolation of the 1.4 kb *NheI*/*HindIII* fragment encoding the C-terminal part of α -agglutinin has been described in EXAMPLE 1. The plasmid pUR2980 contains a 1.25 kb cDNA fragment cloned into the *SmaI* site of commercially available pUC18, which (synthetically synthesizable) fragment encodes the complete coding sequence of triglyceride lipase of *Rhizomucor miehei* (see reference 20), an enzyme used in a number of processes to interesterify triacylglycerols (see reference 21) or to prepare biosurfactants (see reference 22). Beside the 269 codons of the mature lipase molecule, the fragment also harbours codons for the 24 amino acid signal peptide as well as 70 amino acids of the propeptide. PCR can easily be applied to ensure the proper fusion of the gene fragment encoding the mature lipase to the *SUC2* signal sequence or the prepro α -mating factor sequence of *S. cerevisiae*, as well as the in-frame fusion to the described *NheI*/*HindIII* fragment. The following two primers, lipo5 (see SEQ ID NO: 17) and lipo6 (see SEQ ID NO: 20), will generate a 833 bp DNA fragment, which after Proteinase K treatment and digestion with *EagI* and *NheI* can be cloned as an 816 bp long fragment into the *EagI*/*NheI* digested plasmids pUR2972 and pUR2973, respectively (see Figure 7).

[0071] These new *S. cerevisiae* expression plasmids contain the *GAL7* promoter, the invertase signal sequence (pUR2981) or the prepro- α -mating factor sequence (pUR2982), the chimeric *Rhizomucor miehei* lipase/ α -agglutinin gene, the 2 μ m sequence, the defective (truncated) *Leu2* promoter and the *Leu2* gene. These plasmids can be transformed into *S. cerevisiae* and grown and analyzed using protocols described in earlier EXAMPLES.

EXAMPLE 6 Immobilized *Aspergillus niger* glucose oxidase/GPI anchored cell wall proteins on the surface of *S. cerevisiae*

[0072] Glucose oxidase (β -D:oxyggen 1-oxidoreductase, EC 1.1.3.4) from *Aspergillus niger* catalyses the oxidation of β -D-glucose to glucono- δ -lactone and the concomitant reduction of molecular oxygen to hydrogen peroxide. The fungal enzyme consists of a homodimer of molecular weight 150,000 containing two tightly bound FAD co-factors. Beside the use in glucose detection kits the enzyme is useful as a source of hydrogen peroxide in food preservation.

The gene was cloned from both cDNA and genomic libraries, the single open reading frame contains no intervening sequences and encodes a protein of 605 amino acids (see reference 23).

[0073] With the help of two proper oligonucleotides the coding part of the sequence is adjusted in a one-step modifying procedure by PCR in such a way that a fusion gene product will be obtained coding for glucose oxidase and the C-terminal cell wall anchor of the *FLO1* gene product or α -agglutinin. Thus, some of the plasmids described in former EXAMPLES can be utilized to integrate the corresponding sequence in-frame between one of the signal sequences used in the EXAMPLES and the *NheI/HindIII* part of the AGa 1 gene.

[0074] Since dimerisation of the two monomers might be a prerequisite for activity, in an alternative approach the complete coding sequence for glucose oxidase without the GPI anchor can be expressed in *S. cerevisiae* transformant which already contains the fusion construct. This can be fulfilled by constitutive expression of the fusion construct containing the GPI anchor with the help of the *GAPDH* or *PGK* promoter for example. The unbound not-anchored monomer can be produced by using a DNA construct comprising an inducible promoter, as for instance the *GAL7* promoter.

EXAMPLE 7 Process to convert raffinose, stachyose and similar sugars in soy extracts with α -galactosidase/ α -agglutinin immobilized on yeasts

[0075] The yeast transformed with plasmid pUR2969 can be cultivated on large scale. At regular intervals during cultivation the washed cells should be analyzed on the presence of α -galactosidase activity on their surface with methods described in EXAMPLE 1. When both cell density and α -galactosidase activity/biomass reach their maximum, the yeast cells can then be collected by centrifugation and washed. The washed cells can then be added to soy extracts. The final concentration of the yeast cells can vary between 0.1 and 10 g/l, preferably the concentration should be above 1 g/l. The temperature of the soy extract should be $< 8^{\circ}\text{C}$ to reduce the metabolic activity of the yeast cells. The conversion of raffinose and stachyose can be analyzed with HPLC methods and after 95 % conversion of these sugars the yeasts cells can be removed by centrifugation and their α -galactosidase activity/g biomass can be measured. Centrifugates with a good activity can be used in a subsequent conversion process, whereas centrifugates with an activity of less than 50 % of the original activity can be resuscitated in the growth medium and the cells can be allowed to recover for 2 to 4 hours. Thereafter the cells can be centrifuged, washed and subsequently be used in a subsequent conversion process.

EXAMPLE 8 Production of biosurfactants using *Humicola* lipase/ α -agglutinin immobilized on yeasts.

[0076] The yeast transformed with plasmid pUR2972 or pUR2973 can be cultivated on large scale. At regular intervals during cultivation the washed cells can be analyzed on the presence of lipase activity on their surface with methods described in EXAMPLE 1. When both cell density and lipase/biomass reach their maximum, the yeast cells can be collected by centrifugation and washed. The washed cells can be suspended in a small amount of water and added to a reactor tank containing a mix of fatty acids, preferably of a chain length between 12-18 carbon atoms and sugars, preferably glucose, galactose or sucrose. The total concentration of the water (excluding the water in the yeast cells) might be below 0.1 %. The final concentration of the yeast cells can vary between 0.1 and 10 g/l, preferably the concentration is above 1 g/l. The tank has to be kept under an atmosphere of N_2 and CO_2 in order to avoid oxidation of the (unsaturated) fatty acids and to minimize the metabolic activity of the yeasts. The temperature of mixture in the tank should be between $30-60^{\circ}\text{C}$, depending on type of fatty acid used. The conversion of fatty acids can be analyzed with GLC methods and after 95 % conversion of these fatty acids the yeasts cells can be removed by centrifugation and their lipase activity/g biomass can be measured. Centrifugates with a good activity can be used in a subsequent conversion process, whereas centrifugates with an activity of less than 50 % of the original activity can be resuscitated in the growth medium and the cells can be allowed to recover for 2 to 8 hours. Thereafter the cells can be centrifuged again, washed and used in a subsequent conversion process.

EXAMPLE 9 Production of special types of triacylglycerols using *Rhizomucor miehei* lipase/ α -agglutinin immobilized on yeasts.

[0077] The yeast transformed with plasmid pUR2981 or pUR2982 can be cultivated on a large scale. At regular intervals during cultivation the washed cells can be analyzed on the presence of lipase activity on their surface with methods described in EXAMPLE 1. When both cell density and lipase/biomass reach their maximum, the yeast cells can be collected by centrifugation and washed. The washed cells can be suspended in a small amount of water and can be added to a reactor tank containing a mix of various triacylglycerols and fatty acids. The total concentration of the water (excluding the water in the yeast cells) might be below 0.1 %. The final concentration of the yeast cells can vary between 0.1 and 10 g/l, preferably the concentration is above 1 g/l. The tank has to be kept under an atmosphere

in YP medium including galactose as inductor.

[0082] The expression, secretion, localization and activity of the chimeric lipase/FLO1 protein can be analyzed using similar procedures as given in Example 1.

Claims

50

1. Use of a lower eukaryote selected from the group consisting of yeasts and fungi containing an expressible first polynucleotide comprising a structural gene encoding a protein providing catalytic activity, said protein being immobilised at the exterior of the cell wall of said lower eukaryote, and at least part of a gene encoding an anchoring protein capable of anchoring in the cell wall of said lower eukaryote, said part encoding at least the anchoring part of said anchoring protein, which anchoring part is derivable from the C-terminal half of said anchoring protein, said first polynucleotide being present in either a vector or in a chromosome of said lower eukaryote, for carrying out an enzymatic process, by contacting a substrate for the protein providing catalytic activity, with the lower eukaryote.

55

2. Use according to claim 1 wherein the lower eukaryote is selected from the group consisting of yeasts belonging to the genera *Candida*, *Debaryomyces*, *Hansenula*, *Kluyveromyces*, *Pichia* and *Saccharomyces* and fungi belonging to the genera *Aspergillus*, *Penicillium* and *Rhizopus* can be used.
- 5 3. Use according to claim 1 or 2 wherein the protein capable of anchoring in the cell wall is selected from the group consisting of, AGA1 (=a-agglutinin) of *S. cerevisiae*, FLO1 (= flocculation protein), Major Cell Wall Protein of lower eukaryotes, selected from the group consisting of yeasts and fungi.
- 10 4. Use according to any of claims 1-3 wherein the protein providing catalytic activity is selected from the group consisting of hydrolytic enzymes including lipases and oxidoreductases including oxidases.
5. Use according to claim 1 wherein said lower eukaryote further comprises a sequence encoding a signal peptide ensuring secretion of the expression product of said first polynucleotide.
- 15 6. Use according to claim 5, wherein the protein providing catalytic activity exhibits said catalytic activity when present in a multimeric form, said lower eukaryote further comprising a second polynucleotide comprising a structural gene encoding the same protein providing catalytic activity combined with a sequence encoding a signal peptide ensuring secretion of the expression product of said second polynucleotide, said second polynucleotide being operably linked to a regulatable promoter.
- 20

Revendications

- 25 1. Utilisation d'un eucaryote inférieur choisi dans l'ensemble comprenant les levures et les champignons, contenant un premier polynucléotide exprimable comprenant un gène de structure codant pour une protéine assurant une activité catalytique, ladite protéine étant immobilisée à l'extérieur de la paroi cellulaire dudit eucaryote inférieur, et au moins une partie d'un gène codant pour une protéine d'ancrage capable de s'ancrer dans la paroi cellulaire dudit eucaryote inférieur, ladite partie codant pour au moins la partie d'ancrage de ladite protéine d'ancrage, laquelle partie d'ancrage peut être obtenue à partir de la moitié C-terminale de ladite protéine d'ancrage, ledit premier polynucléotide étant présent dans un vecteur ou dans un chromosome dudit eucaryote inférieur, pour mettre en oeuvre un procédé enzymatique, par mise en contact, avec l'eucaryote inférieur, d'un substrat pour la protéine assurant l'activité catalytique.
- 30 2. Utilisation selon la revendication 1, pour laquelle l'eucaryote inférieur est choisi dans l'ensemble comprenant les levures appartenant aux genres *Candida*, *Debaryomyces*, *Hansenula*, *Kluyveromyces*, *Pichia* et *Saccharomyces*, et les champignons appartenant aux genres *Aspergillus*, *Penicillium* et *Rhizopus*.
- 35 3. Utilisation selon la revendication 1 ou 2, pour laquelle la protéine capable de s'ancrer dans la paroi cellulaire est choisie dans l'ensemble comprenant l'AGA1 (= a-agglutinine) de *S. cerevisiae*, le FLO1 (= protéine de floculation), la protéine majeure de paroi cellulaire des eucaryotes inférieurs choisis dans l'ensemble comprenant les levures et les champignons.
- 40 4. Utilisation selon l'une quelconque des revendications 1 à 3, pour laquelle la protéine assurant l'activité catalytique est choisie dans l'ensemble comprenant les enzymes hydrolytiques, parmi lesquelles les lipases, et les oxydoréductases, parmi lesquelles les oxydases.
- 45 5. Utilisation selon la revendication 1, pour laquelle ledit eucaryote inférieur comprend en outre une séquence codant pour un peptide signal assurant la sécrétion du produit d'expression dudit premier polynucléotide.
- 50 6. Utilisation selon la revendication 5, pour laquelle la protéine assurant l'activité catalytique présente ladite activité catalytique quand elle est présente sous une forme multimère, ledit eucaryote inférieur comprenant en outre un deuxième polynucléotide comprenant un gène de structure codant pour la même protéine assurant l'activité catalytique, en combinaison avec une séquence codant pour un peptide signal assurant la sécrétion du produit d'expression dudit deuxième polynucléotide, ledit deuxième polynucléotide étant lié d'une manière opérationnelle à un promoteur régulable.
- 55

Patentansprüche

1. Verwendung eines niederen Eukaryoten, ausgewählt aus der Gruppe, die aus Hefen und Pilzen besteht, enthaltend ein exprimierbares erstes Polynucleotid, umfassend ein Struktur-Gen, das ein Protein mit katalytischer Aktivität kodiert, wobei das Protein im Außenbereich der Zellwand des niederen Eukaryoten immobilisiert ist, und mindestens ein Teil eines Gens, kodierend für ein Ankerprotein, das zum Verankern in der Zellwand des niederen Eukaryoten fähig ist, wobei der Teil zumindest den Ankerteil des Ankerproteins kodiert, wobei der Ankerteil aus der C-terminalen Hälfte des Ankerproteins ableitbar ist, wobei das erste Polynucleotid entweder in einem Vektor oder in einem Chromosom des niederen Eukaryoten vorliegt, zum Durchführen eines enzymatischen Verfahrens, in dem ein Substrat für das die katalytische Aktivität aufweisende Protein mit dem niederen Eukaryoten in Kontakt gebracht wird.
2. Verwendung gemäß Anspruch 1, wobei der niedere Eukaryot aus der Gruppe ausgewählt ist, die aus Hefen besteht, die zu den Genera *Candida*, *Debaryomyces*, *Hansenula*, *Kluyveromyces*, *Pichia* und *Saccharomyces* gehört, und Pilze verwendet werden können, die zu den Genera *Aspergillus*, *Penicillium* und *Rhizopus* gehören.
3. Verwendung gemäß Anspruch 1 oder 2, wobei das zur Verankerung in der Zellwand fähige Protein aus der Gruppe ausgewählt ist, die besteht aus: AGA1 (=α-Agglutinin) von *S. cerevisiae*, FLO1 (= Flokkulationsprotein), Major-Cell-Wall-Protein von niederen Eukaryoten, ausgewählt aus der Gruppe, die aus Hefen und Pilzen besteht.
4. Verwendung gemäß mindestens einem der Ansprüche 1 bis 3, wobei das eine katalytische Aktivität bereitstellende Protein aus der Gruppe ausgewählt ist, die aus hydrolytischen Enzymen, einschließlich Lipasen, und Oxidoreduktasen, einschließlich Oxidasen, besteht.
5. Verwendung gemäß Anspruch 1, wobei der niedere Eukaryot darüber hinaus eine Sequenz umfasst, die ein Signalpeptid kodiert, das die Sekretion des Expressionsproduktes des ersten Polynucleotids sicherstellt.
6. Verwendung gemäß Anspruch 5, wobei das die katalytische Aktivität bereitstellende Protein die katalytische Aktivität zeigt, wenn es in multimerer Form vorliegt, wobei der niedere Eukaryot darüber hinaus ein zweites Polynucleotid umfasst, umfassend ein Struktur-Gen, das das gleiche Protein mit katalytischer Aktivität in Kombination mit einer Sequenz kodiert, die für ein Signalpeptid kodiert, das die Sekretion des Expressionsproduktes des Polynucleotids sicherstellt, wobei das zweite Polynucleotid operabel mit einem regulierbaren Promotor verbunden ist.

CONSTRUCTION OF pUR2990

PCR with oligonucleotides pcrflo1 & pcrflo2
 Isolate 1950 bp fragment
 cut with NheI and HindIII
 ligate into HindIII/ NheI (p) digested pUR2972
